
Project Description: Electrostatic Pump (Open Patent)

The term **electrostatic pump** is used in the description of this project. This is a device that alters the intensity of an electrostatic field in one point of space by increasing it in another. At this stage, we are discussing the field intensity itself without considering the specific matter located within it; every substance reacts uniquely to electrostatic influence, and a separate review will be provided for each example.

Additionally, the term **electrostatic valve** (or coaxial diode) is used. This refers to an asymmetrical construction that utilizes the property of a field to flow from a sharp point to a flat surface more efficiently than in the opposite direction.

Principle of Operation and Construction

Externally, the static pump resembles an influence machine (Wimshurst machine), of which many varieties exist depending on the intended task. The operation of our machine can be explained by the principle of an **electrostatic generator** based on a charge accumulation circuit using a transport mechanism.

- **Charge Transport:** In our case, a circular disk made of Plexiglass or plastic is used. It becomes charged in one location, transports the charges, and releases them in another.
- **Source and Sink:** Based on the fact that the atmosphere carries a positive charge and the earth carries a negative charge, the electrostatic pump receives charge from the atmosphere and delivers it toward the earth.
- **Inlet and Outlet:** The inlet from the atmosphere consists of a toroid or sphere followed by sharp needles that transfer the charge to the plastic disk. The outlet is on the opposite side of the disk, where spherical receivers collect the charge.
- **Accumulation:** This charge then settles in a **Leyden jar** connected between the electrostatic pump and the ground.

To optimize the process, asymmetrical electrostatic valves are placed:

1. Between the atmospheric sphere and the electrostatic pump.
2. Between the receiver (Leyden jar) and the electrostatic pump.

Practical Applications

The primary purpose of this energy is to drive chemical and physical reactions:

1. **Brown's Gas:** Since water has high electrostatic permeability, water placed between two electrodes can be viewed as a capacitor plate. When excess voltage is applied, this "plate" begins to degrade, releasing Brown's gas.
2. **Moisture Management:**
 - *Polarization:* Giving additional energy to micro-particles of moisture in the air so they rise into the atmosphere and are dispersed by the wind.
 - *Coagulation:* Conversely, removing the charge from passing moisture micro-particles to trigger condensation and collection.

3. **Battery Restoration:** It can be used for the chemical recovery of power sources by applying impulsive discharges to them.

Philosophy of the Project

This electrostatic pump is a prototype designed to explain the physics of the process. The next stage involves moving from a mechanical static pump to the use of **electronics** to achieve the same effect.

All described principles are **nature-like** (biomimetic) and do not harm the environment; this is how everything is arranged on planet Earth. Just as fish live in water, all creatures on Earth live within an electrostatic field and are adapted to it. The movement of water in the atmosphere and the growth of trees all function on the principles of electrostatics.

I have recorded this thought as an **Open Patent**—it is the heritage of humanity, released for free use.
